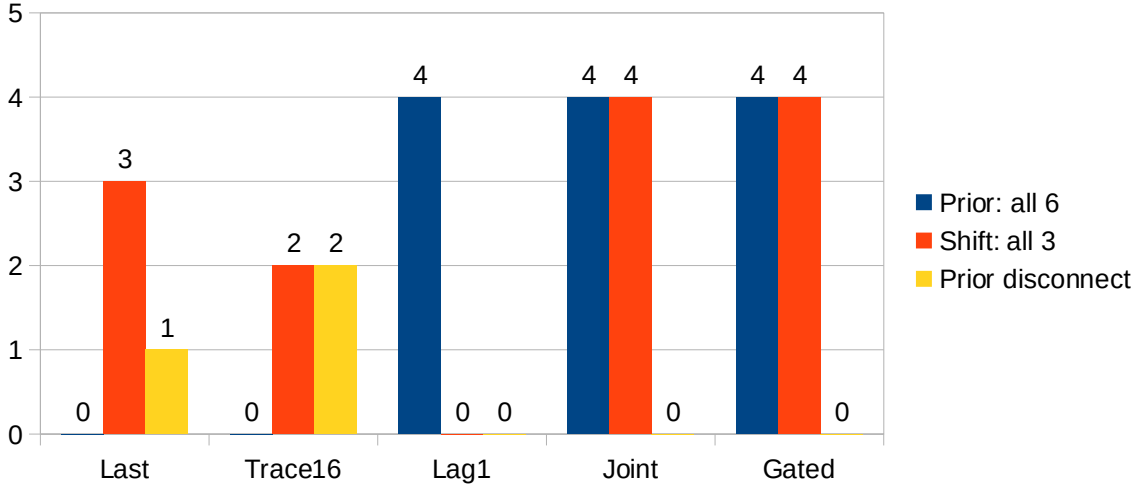
Reassigning credit when the predictive time source changes

Cue meaning reverses first; feedback source changes later, in the same surviving bodies.

A Same event history, two distinct changes

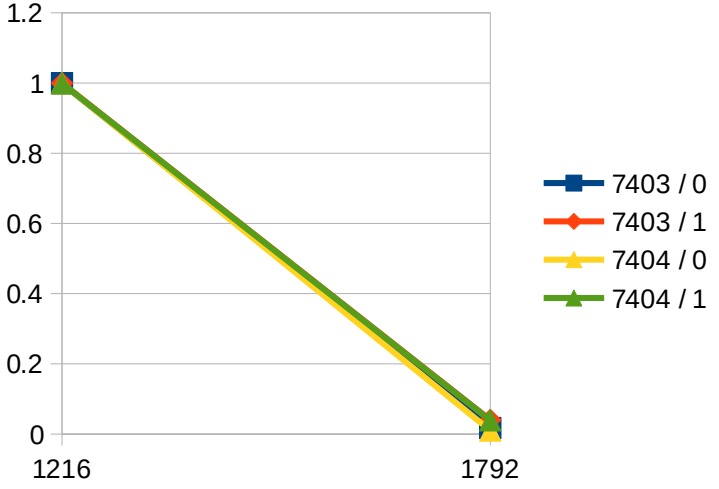
Meaning flip at 640: cue meanings swap; the EARLY event still predicts the outcome.
Source shift at 1216: EARLY → RECENT; cue meaning fixed; 17 surviving parents continue.

B All-probe pass counts, from 4 original conditions



Shift: Last 3/3; Trace16 2/2 among survivors. Prior failures stay excluded.
Joint and Gated: 4/4 in both stages; no advantage of gating established.

C Old-source gate weight



0.99925–0.99952 → 0.00996–0.04007
Lines join endpoints, not a sampled time curve.

First new-source probe follows 16 feedback pulses. Probe endpoint = favourable-cue contact-mass share, not phase accuracy.
