Experience places births, but does not beat current inventory

Equal actual birth mass separates where new material is placed from how much is born.

A Local history sets a gate; the host matches the birth quantity

Paid local intake

n/d | n/d | n/d → **Local gate g_i** → **Weights $q_i \times g_i$** → **Equal $\Sigma born_i = B$**

Old carrier; α = 0.4
Newborn: no past

EMA history or
instant inventory

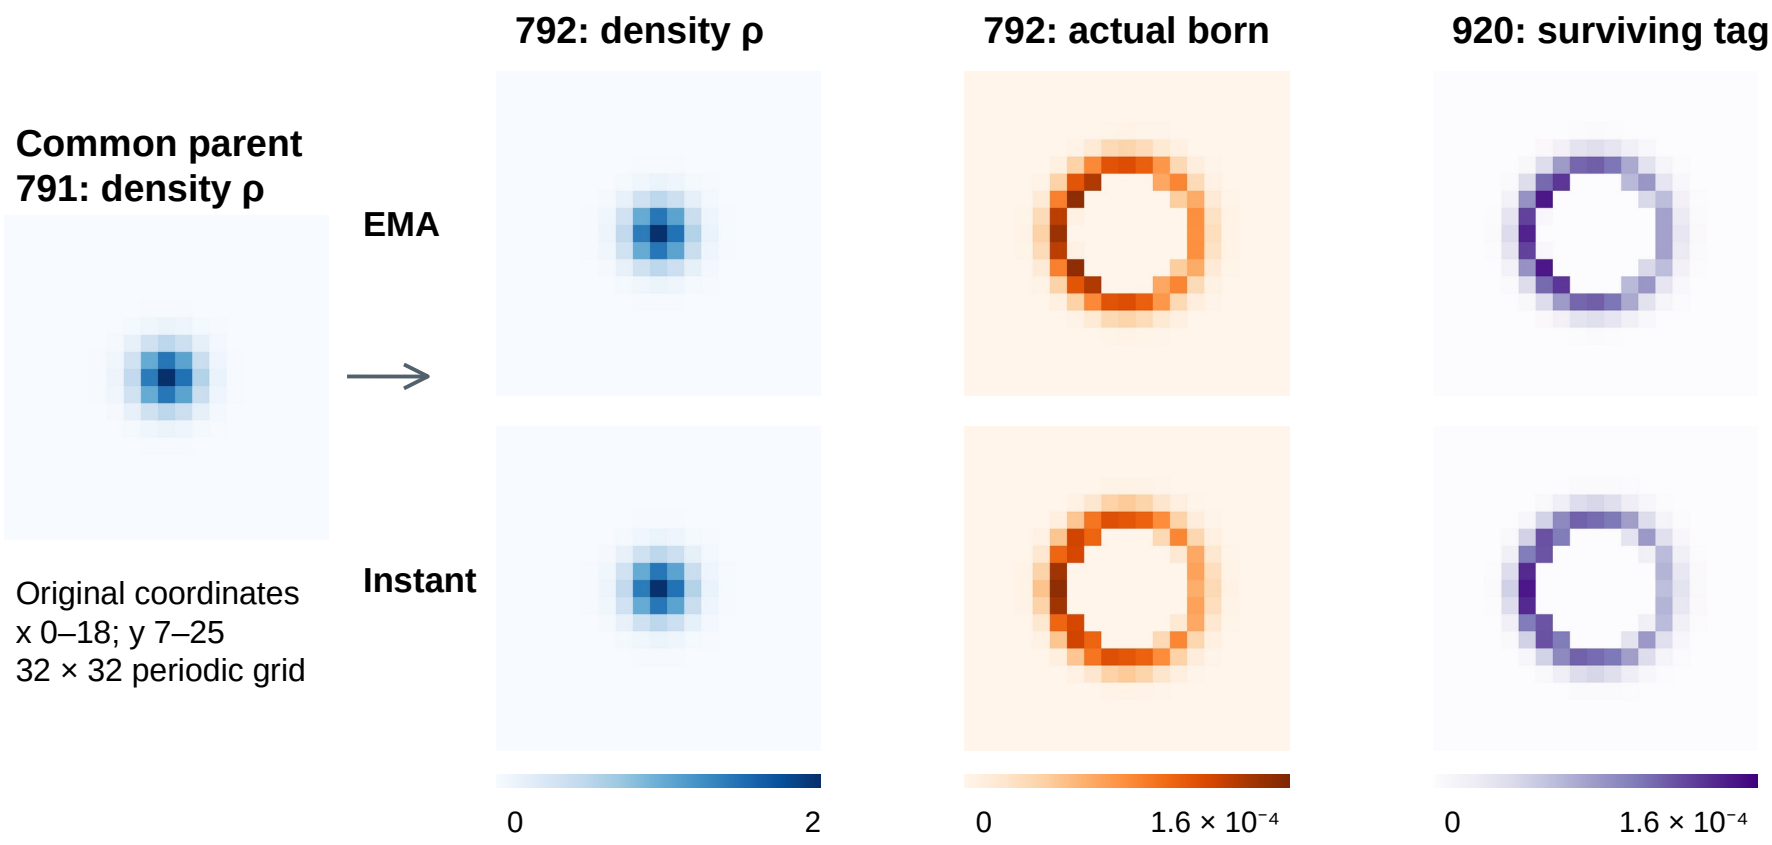

q_i: actual precursor
Uniform: weights q_i

Normalize each layout
Same B within a pair

Hand-set updater • shared E • external movement • imposed M20 • following 128 steps: all-open

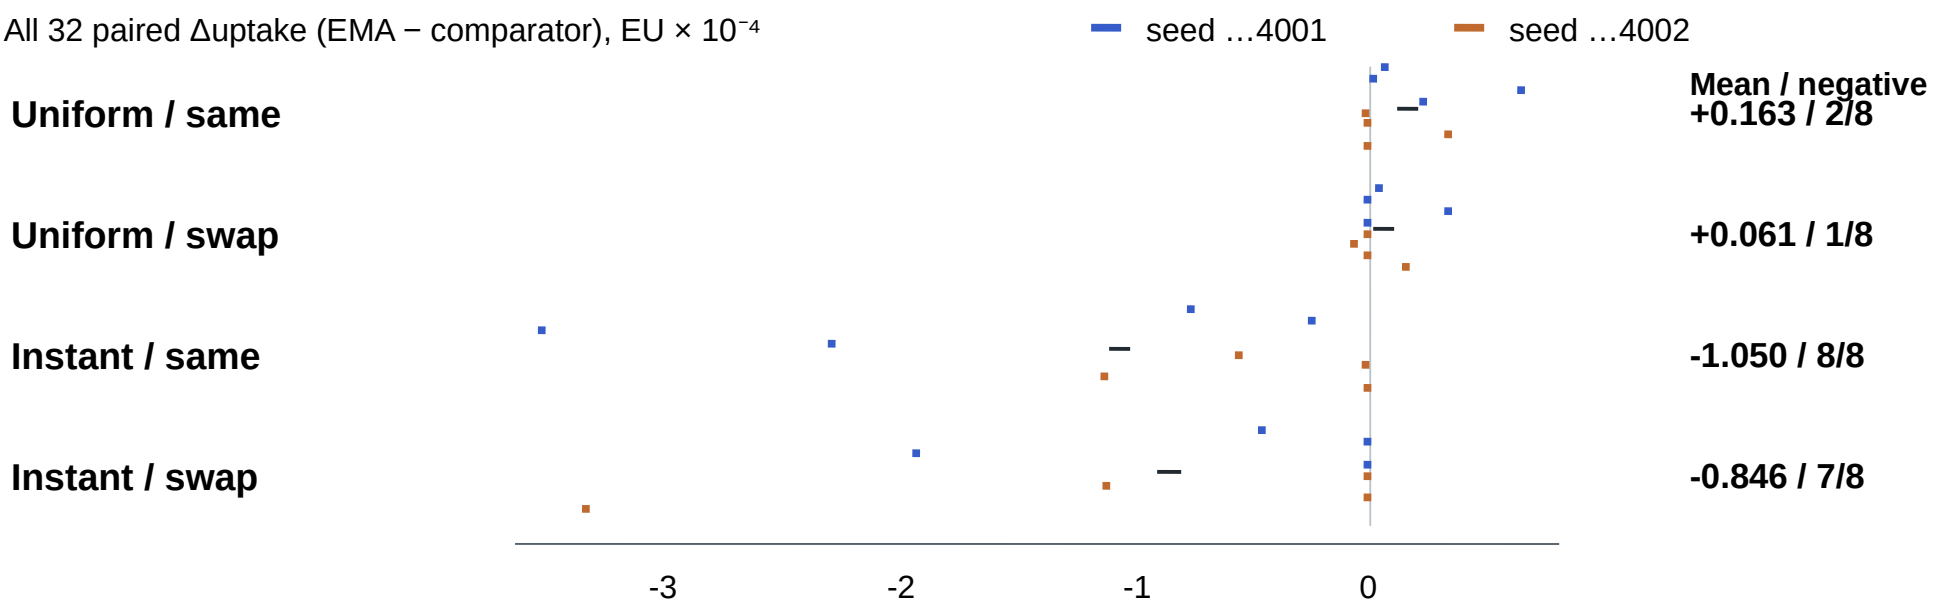

B A small spatial difference at equal birth mass

Predeclared compact / seed …4001 / same / cycle 24. Both layouts: B = 0.004 (0.02% of M20).

Separate density / born / tag scales. Tag describes later contact; pulse uptake occurs before birth.

C Equal-birth placement does not beat instant inventory

Two environment seeds × two shapes × two clocks; dependent pairs. B ranges 8.31 × 10⁻⁷ to 0.004.

Uniform comparison: tiny mean intake gains; mass / body-time mixed. No new form or maintenance advantage.
