TAU SYNTHETIC SAMPLE

Synthetic A-B Study

[TAU:testrun_3d338aadaf2e18c7:workflow.paper] Synthetic A-B Study

TAU SYNTHETIC SAMPLE. This is an invented two-page interface acceptance fixture, not a real scientific paper. Author: Portal TAU Synthetic Author. Year: 2026. No external research results, human participants, or real measurements are used. All values are explicitly fabricated for testing.

Abstract. We construct two fictional groups of three entries each. Every entry in group A has a score of 10 units, and every entry in group B has a score of 12 units. The mean difference is 2 units. The relative change compared with A is 20 percent. This deterministic data has no noise by construction. It cannot establish an effect on real systems.

Research question. Can the Portal Paper interface preserve a synthetic document, extract its registration information, describe its simple experiment table, and display the same chart faithfully after navigation and refresh? The scientific-looking presentation serves only as a controlled test input. It does not support publication claims or comparisons to real models.

Method. We define a baseline function returning 10 and a second condition returning baseline plus 2. We evaluate each function at three arbitrary index values, 1, 2, and 3. The sample size is three per group, with no random sampling, uncertainty estimates, or independent replication. The arithmetic is exact. Group A has mean 10, group B has mean 12, and both have standard deviation zero.

Experiment. Table 1 on page 2 gives the three invented observations, the arithmetic means, and their units. Figure 1 displays the two means as blue and orange bars. The vertical axis begins at zero and is labeled Arbitrary score. Each bar carries its numeric value. The caption states that all observations are fictional. A correct figure explanation should mention the 10 versus 12 comparison and the absence of real-world inference.

Limitations. There is no real dataset, trained model, hardware benchmark, human study, or measured causal effect. The fixed difference of two units is imposed by the function definition. Three identical observations do not estimate variability in any population. AI review should identify these limitations and distinguish an interface fixture from scientific evidence. No citations are invented.

Persistence acceptance. Registration metadata and the actual summary should retain the synthetic label. Deep reading, review, experiment extraction, figure explanation and generation should produce real stored artifacts for this fixture alone. A failed record must remain a failure after refresh. The research chat is limited to a brief question about the fixture. The complete run marker above identifies the authorized test scope.

TAU SYNTHETIC SAMPLE - EXPERIMENT

Table 1. Fictional deterministic observations (arbitrary units)

Group	Index 1	Index 2	Index 3	Mean
A	10	10	10	10
B	12	12	12	12

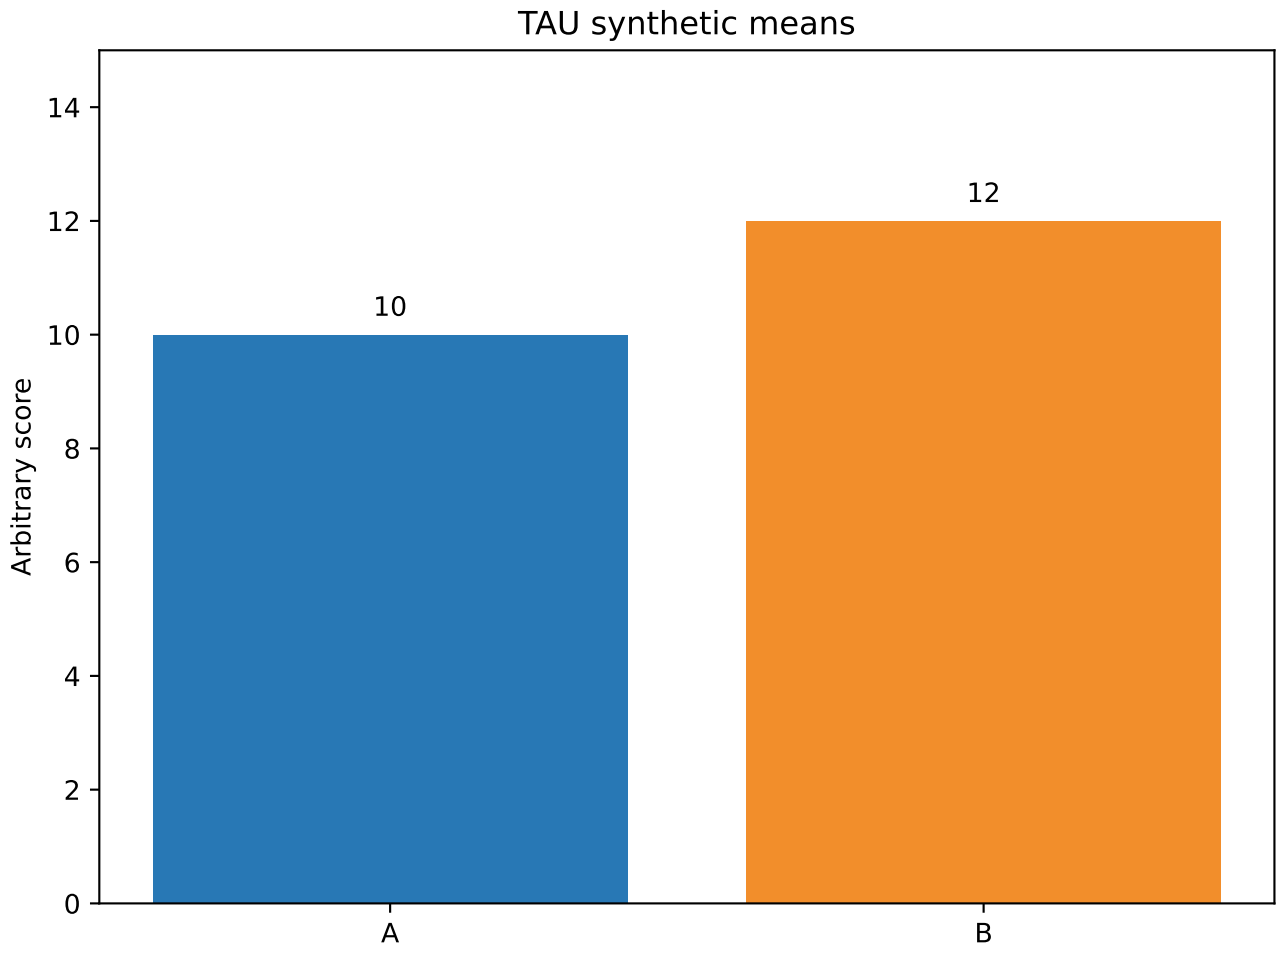

Figure 1. Deterministic synthetic means: A=10, B=12.

FICTIONAL DATA - NO REAL-WORLD INFERENCE
